6 June 2017

## WHERE WERE WE?

- Classification of knots- using knot invariants!
- Q How can we get better invariants?  
A By upgrading/categorifying old ones!
- Khovanov link homology lifts the Jones polynomial.

$$J(L)(q) = \sum_j \left( \sum_i (-1)^i \text{rk Kh}(L) \right) q^j = \chi(Kh(L))$$

skein relation  $\iff$  long exact sequence of  $\text{Kh}(L)$

- Q Why does the choice of algebra  $A$  make sense?  
A1 It's graded dimension is  $J(\bigcirc)$   
A2 Frobenius algebra structure is an algebraic counterpart of the topology of 2d TQFT.

# KHOVANOV HOMOLOGY IS STRONGER THAN THE JONES POLYNOMIAL

| $Kh(5_1)$    |     | $\mathbf{i}$ |                |              |                |    |              |

|                | -3  |              |                |              |                                  |                |                | $\mathbb{Z}_2$ | $\mathbb{Z}$ |
|                | -5  |              |                |              |                                  | $\mathbb{Z}$   | $\mathbb{Z}^2$ |                |              |
|                | -7  |              |                |              | $\mathbb{Z}$                     | $\mathbb{Z}_2$ | $\mathbb{Z}_2$ |                |              |
|                | -9  |              |                |              | $\mathbb{Z} \oplus \mathbb{Z}_2$ | $\mathbb{Z}$   |                |                |              |
|                | -11 |              | $\mathbb{Z}$   | $\mathbb{Z}$ |                                  |                |                |                |              |
|                | -13 |              | $\mathbb{Z}_2$ |              |                                  |                |                |                |              |
|                | -15 | $\mathbb{Z}$ |                |              |                                  |                |                |                |              |

- Torsion is invisible for the Jones!
- $Kh(K)$  can have non-trivial groups of the same rank in gradings of different parity! They cancel out in the Euler characteristic.

# KHOVANOV HOMOLOGY DIFFERENT COEFFICIENTS

- So far:  $Kh(K, \mathbb{Z})$  and  $Kh(K, \mathbb{Q})$
- Next:  $Kh(K, \mathbb{Z}_p)$  and  $Kh(K, \mathbb{Z}_2)$  in particular.
- How do these homologies relate?

## THEOREM (UNIVERSAL COEFFICIENT THEOREM)

$$H^n(C, \mathbb{Z}_p) \cong H^n(C, \mathbb{Z}) \otimes \mathbb{Z}_p \oplus \text{Tor}(H^{n+1}(C), \mathbb{Z}_p)$$

*Or in the language of Khovanov link homology:*

$$Kh^{i,j}(K, \mathbb{Z}_p) \cong Kh^{i,j}(K, \mathbb{Z}) \otimes \mathbb{Z}_p \oplus \text{Tor}(Kh^{i+1,j}(K, \mathbb{Z}_p))$$

## HOW TO COMPUTE?

$\text{Tor}(A, B) = 0$  if  $A$  or  $B$  is free or torsion-free,  $\text{Tor}(\mathbb{Z}_p, \mathbb{Z}_q) = \mathbb{Z}_{\text{GCD}(p,q)}$   
 $\mathbb{Z} \otimes \mathbb{Z}_p = \mathbb{Z}_p$ ,  $\mathbb{Z}_p \otimes \mathbb{Z}_q = \mathbb{Z}_{\text{GCD}(p,q)}$ ,  $\mathbb{Z}_2 \otimes \mathbb{Z}_3 = 0$ ,  $\mathbb{Z}_6 \otimes \mathbb{Z}_4 = \mathbb{Z}_2$

# ODD, EVEN, UNIFIED KHOVANOV

$Kh$  Even (standard) Khovanov homology

$Kh_o$  Odd (Ozsváth, Rasmussen, Szabó 2007)

$Kh_u$  Unified theory over  $R = \mathbb{Z}[\varepsilon]/(\varepsilon^2 - 1)$  (Putyra, 2010)

$\text{MOD } \mathbb{Z}_2$  even or odd theory computed over  $\mathbb{Z}_2$

## RELATIONS BETWEEN THEORIES

- $Kh(L, \mathbb{Z}_2) \cong Kh_o(L, \mathbb{Z}_2)$
- If  $D'$  is the mirror of  $D$  then
  - Both Khovanov chain complexes and homologies are dual.
  - In odd Khovanov this is true only for homology.
- $C_u^{i,j}/(\varepsilon - 1) \cong C^{i,j}$  and  $C_u^{i,j}/(\varepsilon + 1) \cong C_o^{i,j}$  (Putyra, 2010)
- Computing  $Kh_u$  requires classification of R-modules...

# INVARIANTS IN FORM OF HOMOLOGICAL OPERATIONS

- Algebraic operations on  $Kh$  and  $Kh_o$  arising from the action of  $Kh_u$  are link invariants!
- Trivial for alternating knots.
- Computations for all for all prime non-alternating knots with at most 16 crossings by A. Shumakovitch
- Among 201,702 knots with at most 15 crossings (not counting mirror images) there are 99 pairs with the same  $Kh$  and  $Kh_o$  but different homological operations!
- Among 33,672 knots with at most 14 crossings there are 9 pairs with the above property.
- Nothing could distinguish mirror images of these pairs!
- $Kh_u$  is stronger than  $Kh$  and  $Kh_o$  combined!

# REDUCED KHOVANOV HOMOLOGY

$$\widetilde{Kh}(L), \widetilde{Kh}_0(L)$$

- Construction follows that of the corresponding Khovanov homology with one modification
  - Pick a basepoint on the knot diagram away from any crossings
  - Kauffman circle that contains the basepoint is labeled by  $x$
- Reduced Khovanov homologies of a knot do not depend on the position of the basepoint.
- If  $L$  is a link,  $\widetilde{Kh}(L, \mathbb{Z})$  depends on the choice of component the basepoint belongs to, but  $\widetilde{Kh}(L, \mathbb{Z}_2)$  and  $\widetilde{Kh}_0(L, \mathbb{Z})$  do not!
- $Kh(L, \mathbb{Z}_2) \cong \widetilde{Kh}(L, \mathbb{Z}_2) \otimes \mathbb{Z}_2[x]/x^2$  (Shumakovitch, 2004)
- $Kh_0(L, \mathbb{Z}) \cong \widetilde{Kh}_0(L, \mathbb{Z})\{-1\} \oplus \widetilde{Kh}_0(L, \mathbb{Z})\{+1\}$

# HOMOLOGICAL THICKNESS

- $hw_R(K)$  homological width of  $K$  is the minimal number of adjacent diagonals with  $2i - j = \text{const}$  that support  $Kh(K, R)$
- Homological width  $hw_R(K) \geq 2$  is at least two.
- A knot is *thin* if and only if it has homological width 2, otherwise it is *thick*.

| -25 |     | 1  | $7, 3_2$ | $1_2$     |            |            |    |            |            |            |          |          |       |
| -27 |     |    | $4, 1_2$ |           |            |            |    |            |            |            |          |          |       |
| -29 | 1   |    |          |           |            |            |    |            |            |            |          |          |       |

FIGURE:  $Kh(16n197566)$  is thick over  $\mathbb{Z}$  and  $\mathbb{Z}_2$ , while Khovanov homology of the mirror image is thin over  $\mathbb{Z}$  but thick over  $\mathbb{Z}_2$

## DOES THICKNESS CHANGE WITH RESPECT TO $R$ ?

Sometimes. There are examples of knots such that  $hw_{\mathbb{Q}} < hw_{\mathbb{Z}}, hw_{\mathbb{Z}_2}$  and  $hw_{\mathbb{Z}} < hw_{\mathbb{Z}_2}$

# THICKNESS OF THE KHOVANOV HOMOLOGY

- $hw_{\mathbb{Q}}(K_1 \sharp K_2) = hw_{\mathbb{Q}}(K_1) + hw_{\mathbb{Q}}(K_2) - 2$ .
- $K_1 \sharp K_2$  is  $\mathbb{Q}$ -thin if and only if both  $K_1$  and  $K_2$  are  $\mathbb{Q}$ -thin.
- Turaev genus gives an upper bound on homological width of Khovanov homology (Champanerker-Kofman-Stoltzfus, Manturov)

$$hw(L) - 2 \leq g_T(L)$$

- Question: Given a knot do we know if its Khovanov homology is thin or thick?

# BACKGROUND

## SIGNATURE OF A KNOT $\sigma(K)$

is a knot invariant that can be computed from the Seifert surface  $S$ .

- The Seifert form of  $S$  is the pairing  $\phi : H_1(S) \times H_1(S) \rightarrow \mathbb{Z}$  given by taking the linking number  $lk(a^+, b^-)$  where  $a^+, b^-$  indicate the pushoffs in positive and negative directions.
- Given a basis  $\{b_1, \dots, b_{2g}\}$  for  $H_1(S)$  the Seifert form can be represented as a Seifert matrix  $V_{ij} = \phi(b_i, b_j)$
- $\sigma(K)$  is the signature of the matrix  $V + V^\perp$
- $\sigma(K) = \text{signature}(G) - \mu(D)$  (Gordon, Litherland)
- Determinant of  $K$ :  $\det K = |\det G|$

# THICKNESS OF THE KHOVANOV HOMOLOGY

## QUASI-ALTERNATING KNOTS

QA is the smallest set of links that contains the unknot such that if  $L$  is a link which admits a projection with a crossing such that  $L$  is in QA if

- 1 both resolutions  $L_0$  and  $L_\infty$  at that crossing are in QA, and
- 2  $\det(L) = \det(L_0) + \det(L_\infty)$

All alternating knots are in QA

## THEOREM (E.S. LEE 2002)

*Every non-split alternating link is  $R$ -thin for every  $R$ .*

## THEOREM (MANOLESCU-OZSVÁTH, 2007)

*Quasi-alternating links are  $R$ -thin for every  $R$ .*

*Reduced Khovanov homology  $\widetilde{Kh}^{i,j}(L)$  is trivial unless  $2i - j = \sigma(K)$*

# QA-KNOTS ARE THIN

Let  $L = \bigcirc \otimes$ ,  $L_0 = \bigcirc \cup \bigcirc$  and  $L_\infty = \bigcirc \cap \bigcirc$

## LEMMA

If  $\det(L_0), \det(L_\infty) > 0$  and  $\det(L_+) = \det(L_0) + \det(L_\infty)$ , then for  $e = n_-(D_h) - n_+(D_+)$ :  $\sigma(L_0) - \sigma(L_+) = 1$  and  $\sigma(L_\infty) - \sigma(L_+) = e$ .

## PROOF.

Theorem QA knots satisfy the above lemma, so we have the standard Khovanov LES with grading  $\delta = 2i - j$

$$\dots \rightarrow \widetilde{Kh}^{*+\sigma(L_\infty)}(L_\infty) \rightarrow \widetilde{Kh}^{*+\sigma(L)}(L) \rightarrow \widetilde{Kh}^{*+\sigma(L_0)}(L_0) \rightarrow \widetilde{Kh}^{*+\sigma(L_\infty)-1}(L_\infty) \rightarrow \dots$$

- Therefore  $L$  is thin if  $L_0$  and  $L_1$  are thin.
- Apply the same argument to  $L = L_0$  and  $L = L_1$ , apply the Lemma, and repeat iteratively.
- This process ends when we reach the unlink, whose Khovanov homology is thin.

# THICKNESS OF KHOVANOV HOMOLOGY

## THEOREM (E.S. LEE 2002)

*Jones polynomial and signature determine the free part of the Khovanov homology of non-split alternating links.*

## THEOREM (KHOVANOV, 2002)

*Adequate non-alternating knots are known to be R-thick.*

## PROPOSITION

$\widetilde{Kh}^{i,j}(L)$  where  $L$  is an alternating link  $L$  has no 2-torsion.

## PROOF.

Universal coefficient theorem gives us short exact sequences:

$$0 \rightarrow \widetilde{Kh}^{i,j}(L, \mathbb{Z}) \otimes \mathbb{Z}_2 \rightarrow \widetilde{Kh}^{i,j}(L, \mathbb{Z}_2) \rightarrow \mathrm{Tor}(\widetilde{Kh}^{i+1,j}(L, \mathbb{Z}), \mathbb{Z}_2) \rightarrow 0$$

$$0 \rightarrow \widetilde{Kh}^{i-1,j}(L, \mathbb{Z}) \otimes \mathbb{Z}_2 \rightarrow \widetilde{Kh}^{i-1,j}(L, \mathbb{Z}_2) \rightarrow \mathrm{Tor}(\widetilde{Kh}^{i,j}(L, \mathbb{Z}), \mathbb{Z}_2) \rightarrow 0$$

Existence of  $\mathbb{Z}_2$  in  $\widetilde{Kh}^{i,j}(L)$  implies that  $\widetilde{Kh}(L, \mathbb{Z}_2)$  is not thin! □

# PATTERNS IN KHOVANOV HOMOLOGY

Most entries are arranged in "knight move" pairs except two entries in the 0th homological degree. Torsion fits nicely into this pattern...

# KNIGHT MOVE

## CONJECTURE (BAR-NATAN, GAROUFALIDIS, KHOVANOV)

*For every knot  $L$ , the ranks of its Khovanov homology  $Kh(L)$  are arranged in "knight-move" pairs, except for two adjacent entries in the  $i = 0$  column, which have to be decreased by 1.*

## STATUS

- proved for QH-thin knots (Lee, 2002), therefore true for all non-split alternating links and quasi-alternating.
- also true for knots with homology supported on 3 diagonals;
- no counter-example is known

## LEE'S DIFFERENTIAL

- Work over  $\mathbb{Q}$  (and  $\mathbb{Z}_p$  for odd  $p$ ).
- Define  $\mathbb{Q}$ -linear maps

$$\begin{aligned} m_{Lee} : \mathcal{A} \otimes \mathcal{A} &\rightarrow \mathcal{A} & m_{Lee} : \begin{cases} 1 \otimes 1 \mapsto 0 & 1 \otimes x \mapsto 0 \\ x \otimes 1 \mapsto 0 & x \otimes x \mapsto 1 \end{cases} \\ \Delta_{Lee} : \mathcal{A} &\rightarrow \mathcal{A} \otimes \mathcal{A} & \Delta_{Lee} : \begin{cases} 1 \mapsto 0 \\ x \mapsto 1 \otimes 1. \end{cases} \end{aligned}$$

- Lee's differential  $d_{Lee}$  is defined using the maps before and has bidegree  $(1, 4)$  i.e. it does not preserve  $q$ -grading ... but it is a filtered map.
- $(C(L), d, d_{Lee})$  form a double complex...

# BICOMPLEXES

- $(M, d_h, d_v)$  is a double complex if  $M$  is a bigraded module over some ring  $R$  and
  - $d_h, d_v : M \rightarrow M$  are differentials of bidegree  $(1, 0)$  and  $(0, 1)$
  - $d_h, d_v$  anti-commute:  $d_h \cdot d_v + d_v \cdot d_h = 0$
- $d_h$  induces a differential  $d_h^*$  on  $H(M, d_v)$  and so does  $d_v$ .
- Total complex  $(Tot(M), d)$  with  $M$  a graded module over  $R$  with a homogeneous degree  $n$  part of  $Tot(M)$  equal to  $\bigoplus_{k+l=n} M^{k,l}$  and  $d = d_h + d_v$
- $d^2 = d_h^2 + d_h d_v + d_v d_h + d_v^2 = 0$
- There exists a spectral sequence  $\{E_r, d_r\}$  with  $E_0 = M$ ,  $E_1 = H(M, d_h)$ , and  $E_2 = H(H(M, d_h), d_v^*)$ .
- If  $M$  has bounded support, then this spectral sequence converges to  $H(Tot(M), d)$ .

## LEE'S SPECTRAL SEQUENCE

- $(C(L), d, d_{Lee})$  form a double complex so there is an associated spectral sequence.
- The bidegree of the map on the  $r$ -th page of the spectral sequence is  $(1, 4r)$ .
- In all known examples (over  $\mathbb{Q}$ ) the spectral sequence collapses after the bidegree  $(1, 4)$  differential.
- In such cases,  $Kh(D; \mathbb{Q})$  can be arranged into “knight move” pairs.

### THEOREM (E.S. LEE)

Let  $L$  be an oriented  $n$  component link,  $\{S_i\}_{i=1}^n$ .  $\dim Kh_{Lee}(L) = 2^n$  and  $\dim Kh_{Lee}^i = 2 |E \subset \{2, \dots, n\} | (\sum_{j \in E, k \notin E} 2lk(S_j, S_k) = i) |$

# LEE-RASMUSSEN SPECTRAL SEQUENCE

## THEOREM (LEE, RASMUSSEN)

*There is a spectral sequence whose  $E_2$ -term is  $Kh(L)$  which converges to  $Kh_{Lee}(L)$ .*

*For a knot, the spectral sequence converges to  $\mathbb{Q} \oplus \mathbb{Q}$ .*

|              |              |
|--------------|--------------|
|              | $\mathbb{Q}$ |
|              |              |
| $\mathbb{Q}$ |              |

knight move pair

|                |                |
|----------------|----------------|
|                | $\mathbb{Z}_2$ |
| $\mathbb{Z}_2$ | $\mathbb{Z}_2$ |
| $\mathbb{Z}_2$ |                |

tetromino

Shumakovitch  
(2004) showed  
that this spectral  
sequence also  
exists over  $\mathbb{Z}_p$  for  
 $p$  an odd prime.

## RASMUSSEN'S S-INVARIANT

*"In a beautiful article Eun Soo Lee introduced a second differential on the Khovanov complex of a knot (or link) and showed that the resulting (double) complex has non-interesting homology. This is a very interesting result."*

*D. Bar Natan*

- Important: the entire spectral sequence, starting with the  $E^2$ -page is a link invariant
- Only two generators survive in the limit and they are in q-gradings  $s_{max}$  and  $s_{min}$  which differ by 2
- Rasmussen's invariant  $s(K) := \frac{1}{2}(s_{max} - s_{min})$

## RASMUSSEN'S S-INVARIANT

- $s(K)$  is additive
- Taking a mirror of a knot changes the sign of the  $s$ -invariant.
- $s(\bigcirc) = 0$
- $s(K)$  is a concordance invariant (i.e. all concordant knots have the same  $s$ -invariant)
- Slice genus of  $K$  (4-ball genus)  $g^*(K)$  is the minimum genus of a smooth surface smoothly embedded in  $B^4$  whose boundary is  $K$ .

### THEOREM ( RASMUSSEN)

*Rasmussen's  $s$ -invariant provides a lower bound on the slice genus*

$$|s(K)| \leq 2g^*(K)$$

# MILNOR CONJECTURE

## THEOREM ( RASMUSSEN)

*Given a positive knot  $K$  with*

- $n$  crossings and*
- $r$  circles in the canonical homogeneous smoothing*

*then  $s(K) = -r + n + 1$*

## COROLLARY

*Torus knot  $T(p, q)$  is a positive knot and  $s(T(p, q)) = (p - 1)(q - 1)$*

## THEOREM (KRONHEIMER, MROWKA; RASMUSSEN)

*Slice genus of a torus knot  $T(p, q)$  is  $\frac{1}{2}(p - 1)(q - 1)$ .*

# KHOVANOV HOMOLOGY APPLICATIONS

## THEOREM (MROWKA, KRONHEIMER 2010)

*Khovanov homology detects the unknot: if the rank of the reduced Khovanov homology of  $L$  is equal to 1 then  $L$  is the unknot.*

## THEOREM (HEDDEN, NI 2012)

*Khovanov homology detects the 2-component unlink.*

*Note: the Jones polynomial does not. There are infinite families of links whose Jones polynomial is the same as that of an  $n$ -component unlink.*

## THEOREM (BATSON, SEED 2013)

*$Kh(L)$  gives lower bound for splitting number of  $L$ .*

# *Thank you*

*Challenge: Find knots in Freiburg!*
